Hantavirus Pulmonary Syndrome

1. DISEASE REPORTING

A. Purpose of Reporting and Surveillance
   1. To characterize the epidemiology and clinical aspects of this emerging disease.
   2. To monitor disease trends and recognize outbreaks.
   3. To target prevention and control messages.

B. Legal Reporting Requirements
   1. Health care providers: notifiable to local health jurisdiction within 24 hours.
   2. Health care facilities: notifiable to local health jurisdiction within 24 hours.
   3. Laboratories: Hantavirus detection notifiable to local health jurisdiction within 24 hours –
      specimen submission on request but confirmation strongly recommended (see Section 4).
   4. Local health jurisdictions: notifiable to the Washington State Department of Health
      (DOH) Office of Communicable Disease Epidemiology (OCDE) within 7 days of case
      investigation completion or summary information required within 21 days.

C. Local Health Jurisdiction Investigation Responsibilities
   1. Facilitate the transport of specimens to Washington State Public Health Laboratories for
      confirmatory testing.
   2. Report all confirmed cases to OCDE. Use the hantavirus pulmonary syndrome report
      form (www.doh.wa.gov/Portals/1/Documents/5100/210-028-ReportForm-
      Hantavirus.pdf) and enter the data into the Public Health Issues Management System
      (PHIMS).

2. THE DISEASE AND ITS EPIDEMIOLOGY

A. Etiologic Agent
   Multiple hantaviruses have been identified. Sin Nombre virus is the predominant
   hantavirus in North America and is responsible for all cases identified in Washington.

B. Description of Illness
   Hantavirus pulmonary syndrome (HPS) is an acute viral disease characterized by a
   relatively short (3–5 days) prodrome of fever, myalgias (muscle aches), headache, and
   gastrointestinal complaints followed by the abrupt onset of acute respiratory distress
   syndrome (ARDS) and hypotension. The illness progresses rapidly to respiratory failure
   with bilateral pulmonary infiltrates, pulmonary edema, and shock. Circulating
   immunoblasts (immature myelocytes), elevated hematocrit, and thrombocytopenia are
   almost always present; a rapid drop in platelets marks onset of the cardiopulmonary
   phase. About a third of all cases in the United States have died. In survivors, recovery
   from acute illness is rapid, but full convalescence may require weeks or months.
Restoration of normal lung function generally occurs, but pulmonary function abnormalities may persist in some individuals.

C. Hantavirus Pulmonary Syndrome (HPS) in Washington State

Through 2012 there have been 45 reported cases of HPS among Washington residents, 16 (36%) of which were fatal. Additionally there were two cases in foreign nationals working in the state, one of which was fatal. Between one and five cases are reported annually. Cases have occurred throughout most counties, though the majority have exposure in eastern Washington. The median age is 36 years (range 14–75 years).

It is extraordinarily rare to see multiple cases with a single common exposure. We have not seen any clustering of cases in Washington. However, during 2012 there was an outbreak associated with visits to Yosemite National Park in California. A total of 10 cases were identified; 9 stayed in the Signature Tent Cabins and the other had hiked nearby. See: [www.cdc.gov/hantavirus/outbreaks/yosemite-national-park-2012.html](http://www.cdc.gov/hantavirus/outbreaks/yosemite-national-park-2012.html).

D. Reservoirs

The deer mouse (*Peromyscus maniculatus*) is the major reservoir of Sin Nombre virus in the western United States. Deer mice live in all parts of Washington, but mainly in rural areas. The deer mouse is about six inches long from the nose to the tip of its tail. It is grayish to light brown on top, with a white belly, large ears and eyes, and a furry tail that is white on the underside. Deer mice usually carry the virus without showing any signs of being sick.

Rodent serosurveys were conducted in Washington from 1993 to 2001 by various state and federal agencies. During this time period, 14% of over 1,100 deer mice tested in Washington had antibodies against Sin Nombre virus, similar to prevalence in other western states. These data, as well as data from other states, also demonstrated that the percentage of infected mice may fluctuate widely from year to year.

E. Modes of Transmission

Transmission is via inhalation of virus that is excreted in mouse urine, feces or saliva and aerosolized during cleaning of buildings with rodent nests or other rodent contamination. Exposures have occurred in rodent-infested cabins, homes, barns, vehicles, outbuildings or less commonly when handling wild rodents without protective equipment. Nationally, rare transmission has been documented from a bite of a deer mouse.

F. Incubation Period

One to six weeks (7–45 days).

G. Period of Communicability

Person-to-person spread of hantaviruses has not occurred in this country. However, it has been documented in Argentina during an outbreak due to a related Andes virus.
H. Treatment

There is no antiviral treatment. Supportive care including intubation and ventilation and fluid and pharmacologic support of blood pressure is typically required.

3. CASE DEFINITION

A. Clinical Case Definition

1. Non-HPS Hantavirus infection is a febrile illness with non-specific viral symptoms including fever, chills, myalgia, headache, and gastrointestinal symptoms. Typical clinical laboratory findings include hemoconcentration, left shift in the white blood cell count, neutrophilic leukocytes, thrombocytopenia, and circulating immunoblasts.

2. Hantavirus Pulmonary Syndrome (HPS) is an acute febrile illness (i.e., temperature greater than 101.0 F [greater than 38.3 C]) with a prodrome consisting of fever, chills, myalgia, headache, and gastrointestinal symptoms, and one or more of the following clinical features:
   - Bilateral diffuse interstitial edema, OR
   - Clinical diagnosis of acute respiratory distress syndrome (ARDS), OR
   - Radiographic evidence of noncardiogenic pulmonary edema, OR
   - An unexplained respiratory illness resulting in death, and includes an autopsy examination demonstrating noncardiogenic pulmonary edema without an identifiable cause, OR
   - Healthcare record with a diagnosis of hantavirus pulmonary syndrome, OR
   - Death certificate lists hantavirus pulmonary syndrome as a cause of death or a significant condition contributing to death

B. Laboratory Criteria for Diagnosis

1. Detection of hantavirus-specific immunoglobulin M (IgM) or rising titers of hantavirus-specific immunoglobulin G (IgG), OR
2. Detection of hantavirus-specific ribonucleic acid (RNA) in clinical specimens, OR
3. Detection of hantavirus antigen by immunohistochemistry (IHC).

Note: Laboratory testing should be performed or confirmed at a public health reference laboratory. Because the clinical illness is nonspecific and ARDS is common, a screening case definition should be used to determine which patients to test. In general, a predisposing medical condition (e.g., malignancy, chronic pulmonary disease, trauma, burn, or surgery) is a more likely cause of ARDS than HPS. Patients with these underlying conditions and ARDS need not be tested for hantavirus.

C. Case Definition (2015)

Confirmed: a clinically compatible case of HPS or non-HPS Hantavirus infection that is laboratory confirmed.
4. DIAGNOSIS AND LABORATORY SERVICES

A. Laboratory Diagnosis

Positive commercial lab results should be confirmed at a public health reference laboratory such as the Washington State Public Health Laboratories.

Serology: Diagnosis is most commonly made by detection of virus-specific IgM in serum using an enzyme immunoassay (EIA). Most patients have IgM antibodies at time of hospitalization. A test for IgG is used in conjunction with the IgM-capture test. Acute- and convalescent-phase sera should reflect a four-fold rise in IgG antibody titer. An acute-phase serum drawn as an initial diagnostic specimen may not yet have IgG present. IgG antibody is long-lasting once it develops, and sera of patients retrospectively identified appear to have retained antibody for many years.

Reverse transcriptase-polymerase chain reaction (RT-PCR) can be used to detect hantavirus RNA in fresh frozen lung tissue, blood clots, or nucleated blood cells.

Immunohistochemistry (IHC) testing of formalin-fixed tissues or paraffin-embedded tissues with specific monoclonal and polyclonal antibodies can be used to detect hantavirus antigens. IHC can be useful in fatal cases.

To date, no isolates of Sin Nombre virus-like viruses have been recovered from humans, so virus isolation is not a diagnostic consideration. There is no test for exposure to the virus. Decreased platelets or presence of immature cells (myelocytes, metamyelocytes) in the white blood count are suggestive but not diagnostic of hantavirus infection.

Testing mice is not recommended. There is no test to determine if the urine, droppings or nesting material are infectious. Persons concerned about exposure to such materials should monitor themselves and seek medical care if they develop symptoms.

B. Services Available at the Washington State Public Health Laboratories (PHL)

The PHL uses an enzyme immunoassay (EIA) for virus-specific IgM and IgG antibody in serum. RT-PCR and IHC are available through the CDC. All specimens being submitted to CDC must be sent through the PHL. Please call the Office of Communicable Disease Epidemiology (OCDE) for approval and consultation on appropriate specimens prior to submission.

Note that PHL require all clinical specimens have two patient identifiers, a name and a second identifier (e.g., date of birth) both on the specimen label and on the submission form. Due to laboratory accreditation standards, specimens will be rejected for testing if not properly identified. Also include specimen source and collection date.

C. Criteria for Testing HPS Specimens at PHL

1. Patients with suspected hantavirus pulmonary syndrome (i.e., fever, hypotension, hypoxia, bilateral interstitial pulmonary infiltrates, acute respiratory distress syndrome, thrombocytopenia, hemoconcentration without an identifiable cause).

2. Evidence of hantavirus infection based on a positive test from a commercial laboratory.

3. Death due to unexplained respiratory illness with autopsy demonstrating non-cardiogenic pulmonary edema without identifiable cause.
D. Specimen Collection

**Serum**

Submit at least 1 mL (2.5 mL preferred) of serum (not whole blood). Serum can be drawn upon hospital admission. If possible, also obtain as late a serum as available before death or hospital discharge, or a convalescent serum drawn approximately 21 days after the first specimen. Separated serum specimens should be refrigerated and transported cold with regular ice packs. Avoid repeated freeze-thaw cycles, but if specimen is already frozen, then ship on dry ice. Submit specimens with a completed PHL serology form: [http://www.doh.wa.gov/Portals/1/Documents/5230/302-017-SerVirHIV.pdf](http://www.doh.wa.gov/Portals/1/Documents/5230/302-017-SerVirHIV.pdf).

For information on specimens other than serum (tissue, bronchoalveolar lavage, blood clot, etc.), consult OCDE and visit: [http://www.cdc.gov/hantavirus/health-care-workers/specimen-submission/protocol.html](http://www.cdc.gov/hantavirus/health-care-workers/specimen-submission/protocol.html).

5. ROUTINE CASE INVESTIGATION

Interview the case and others who may be able to provide pertinent clinical information.

A. Evaluate the Diagnosis

Obtain and review laboratory reports and medical records. If the case tests positive for hantavirus at a commercial laboratory, facilitate transport of the specimen (i.e., serum or tissue) to Public Health Laboratories for further testing.

B. Manage the Case

Hospitalized patients should be cared for using standard precautions. Person-to-person spread of hantaviruses has not occurred in the U.S. Educate the case about avoiding future exposures (see Section 6B).

C. Identify Potential Sources of Infection

Obtain a history about possible exposure to fresh rodent urine, droppings, or nesting material. Exposures generally occur when urine, droppings, or nesting material are stirred up, aerosolized, and inhaled. A rodent bite can also transmit the virus; however inhaling the virus is a much more common transmission route to humans.

D. Identify Other Potentially Exposed Persons

Identify other persons who may have been in or around the presumed the case’s exposure location, e.g., other household residents, campground staff or residents, or facility employees. Posting a sign in public areas (e.g., campgrounds) may be appropriate.

E. Management of Others Exposed

Other persons who may have been exposed to the same source as the case should be educated regarding avoiding future exposures and the signs of hantavirus pulmonary syndrome. They should be advised to seek medical attention if symptoms develop. However, it is rare to have multiple cases sharing a common exposure.

F. Environmental Evaluation

Notify local environmental health program of locally acquired cases. It may be appropriate to examine the environment where the case was exposed to make suggestions.
about rodent removal. However, since the deer mice are found throughout Washington and are the known reservoir for the Sin Nombre virus, rodent testing is not done.

6. ROUTINE PREVENTION

A. Immunization Recommendations: None

B. Prevention Recommendations

1. **Keep rodents out of your home and workplace.** Always take precautions when cleaning, sealing and trapping in rodent-infested areas.

2. **Seal up** cracks and gaps in buildings that are larger than 1/4 inch including window and door sills, under sinks around the pipes, in foundations, attics, and any rodent entry hole.

3. **Trap indoor rats and mice** with snap traps.

4. **Remove rodent food sources.** Keep food (including pet food) in rodent proof containers.

5. **Clean up rodent infested areas:**
   - Wear rubber, latex, vinyl or nitrile gloves.
   - Do not stir up dust by vacuuming, sweeping, or any other dust-generating means.
   - Thoroughly wet contaminated areas including trapped mice, droppings, nests with a bleach solution or household disinfectant. Hypochlorite (bleach) solution: Mix 1½ cups of household bleach in 1 gallon of water. Use only freshly mixed solution.
   - Once everything is soaked for 10 minutes, remove all of the nest material, mice or droppings with damp towel and then mop or sponge the area with bleach solution or household disinfectant.
   - Spray dead rodents with disinfectant and then double-bag along with all cleaning materials. Bury, burn, or throw out rodent in an appropriate waste disposal system.
   - Disinfect gloves with disinfectant or soap and water before taking them off.
   - After taking off the disinfected gloves, thoroughly wash hands with soap and water (or use a waterless alcohol-based hand rub when soap is not available).

The CDC has additional details: http://www.cdc.gov/hantavirus/hps/prevention.html.

ACKNOWLEDGEMENTS

This document is a revision of the Washington State Guidelines for Notifiable Condition Reporting and Surveillance published in 2002 which were originally based on the Control of Communicable Diseases Manual (CCDM), 17th Edition; James Chin, Ed. APHA 2000. We would like to acknowledge the Oregon Department of Human Services for developing the format and select content of this document.

UPDATES

March 2009: In Section 2C, the number of reported cases and deaths in Washington was updated. In Section 4D, the link for lab form was updated.

January 2010: In Section 2C case numbers were updated and in Section 3A the clinical case definition was revised to reflect the new 2010 CSTE case definition.

January 2011: The Legal Reporting Requirements section has been revised to reflect the 2011 Notifiable Conditions Rule revision. Sections 3B and 4A were modified to reflect that confirmatory testing should be performed at WA PHL or another PHL.
December 2012: Incidence and mortality data were updated (Section 2) The Routine Case Investigation and Controlling Further Spread sections were combined (Section 5).

January 2015: The case definition was updated, and now includes non-HPS Hantavirus infection.
