1. DISEASE REPORTING

A. Purpose of Reporting and Surveillance

1. To assist in the diagnosis and treatment of cases.
2. To identify potentially exposed close contacts, health care workers, and laboratory personnel and to provide counseling.
3. To identify sources of transmission (e.g., wild rodents or other animals) and to prevent further transmission from such sources.
4. To raise suspicion of a possible bioterrorism event if there is no natural exposure source.

B. Legal Reporting Requirements

1. Health care providers: Immediately notifiable to local health jurisdiction.
2. Health care facilities: Immediately notifiable to local health jurisdiction.
3. Laboratories: *Yersinia pestis* immediately notifiable to local health jurisdiction; specimen submission required — culture or other appropriate clinical material (2 business days).
5. Local health jurisdictions: Suspected and confirmed cases are immediately notifiable to the Washington State Department of Health (DOH) Office of Communicable Disease Epidemiology (OCDE) (206-418-5500 or 1-877-539-4344).

C. Local Health Jurisdiction Investigation Responsibilities

1. If bioterrorism is suspected, immediately report the case to DOH: 1-877-539-4344.
2. Facilitate the transport of specimens to Washington State Public Health Laboratories for confirmatory testing.
3. Educate potentially exposed persons about signs and symptoms of disease; recommend antibiotic prophylaxis as needed.
4. Report all suspected, probable and confirmed cases to OCDE (see definitions below). Complete a plague report form (http://www.doh.wa.gov/Portals/1/Documents/5100/210-058-ReportForm-Plague.pdf) and enter the data in the Public Health Issues Management System (PHIMS).

2. THE DISEASE AND ITS EPIDEMIOLOGY

A. Etiologic Agent

*Yersinia pestis* is a non-spore-forming, non-motile Gram-negative coccobacillus with a characteristic “safety pin” appearance due to bipolar staining. *Y. pestis* is viable for weeks in moist conditions and may survive an hour in the air, but is killed by sunlight or heat.
B. Description of Illness

*Yersinia pestis* infection in humans occurs as three clinical forms depending on route of transmission. Overall about 14% of plague cases in the United States are fatal.

1. **Bubonic Plague**

The bubonic form accounts for over 80% of plague cases in the United States. Patients typically experience a sudden onset of fever, headache, chills, and weakness, and one or more swollen, tender and painful lymph nodes. This form is usually the result of an infected flea bite. Symptoms progress rapidly, with development of lymphadenitis, which becomes very painful. These swollen lymph nodes are known as buboes, which are typically found in the inguinal (groin) region, but also the axillary (armpit) or cervical (neck) region. Untreated bubonic plague can progress to cause septicemia or secondary pneumonic plague. Rarely, it progresses to meningitis.

2. **Septicemic Plague**

The primary septicemic form occurs in about 10% of plague cases in the United States. Diagnosis can be difficult because buboes are not seen in primary septicemic plague. Septicemic plague can be secondary to bubonic plague. Fever, chills, extreme weakness, and abdominal pain are common. Patients may progress to endotoxic-shock, disseminated intravascular coagulation (DIC), multiple organ failure, acute respiratory distress syndrome (ARDS), mental confusion, gangrenous extremities (black plague), and death. This form results from bites of infected fleas or from handling an infected animal.

3. **Pneumonic Plague**

About 12% of plague patients in the United States developed pneumonic plague of which around 50% are fatal cases. The pneumonic form of plague usually develops in patients with bubonic or septicemic plague (i.e., secondary pneumonic plague). Primary pneumonic plague results from inhaling infectious droplets in the air and is quite rare, accounting for only 2% of plague cases in this country. Pneumonic plague causes acute onset of fever, chills, headache, weakness, and myalgias, followed within 24 hours by cough with bloody sputum. The pneumonia progresses rapidly, resulting in dyspnea, stridor, and cyanosis, terminating in respiratory failure, circulatory collapse, and death. Pneumonic plague is the most serious form of the disease and is the only form of plague that can be spread from person to person (by infectious droplets).

C. Plague in Washington State

Plague infections of animals occur in the state, mainly in eastern counties but also in western Washington. Statewide serologic sampling of 6,781 wild carnivores between 1975 and 2008 showed 3.3% reactivity (DOH Zoonotic Disease Program data and summary: [http://www.doh.wa.gov/Portals/1/Documents/Pubs/333-161.pdf](http://www.doh.wa.gov/Portals/1/Documents/Pubs/333-161.pdf)) indicating the presence of infected wild rodents. Human plague infections are extremely rare, the last report was an animal trapper exposed while skinning a bobcat in Yakima County in 1984. Nationally, plague occurs mainly in southwestern states with 1-17 cases annually.

D. Vectors and Reservoirs

Wild rodents (especially squirrels, prairie dogs, other burrowing rodents) are the reservoir
of *Y. pestis* which is transmitted by fleas. In eastern Washington the sagebrush vole is the major reservoir; ground squirrels are competent reservoirs in the south central Cascades. *Y. pestis* can spread from rodents to other wildlife, domestic animals, and humans.

E. Modes of Transmission

1. **Flea Bites**
   
   The most common means of transmission to humans is through bites from fleas infected with *Y. pestis*. During plague epizootics, many rodents die, causing fleas to seek other sources of blood. People and animals that visit places where rodents have recently died from plague are at risk of being infected from flea bites. Fleas that feed on plague-infected animals can remain infective for months.

2. **Infected Animals**
   
   Handling tissues of infected rodents or other animals can cause human infection. Cats and dogs naturally infected (due to eating infected rodents or bites by their fleas) ([http://cid.oxfordjournals.org/content/52/2/185.full.pdf+html](http://cid.oxfordjournals.org/content/52/2/185.full.pdf+html)) have been sources of human infections through direct contact, bites and scratches, flea bites by plague-infected fleas carried by domestic animals, and respiratory droplets from animals with pneumonic plague.

3. **Infected Humans**
   
   Person-to-person transmission occurs from patients with pneumonic plague through respiratory droplet spread. Individuals with bubonic plague are infectious when buboes or other cutaneous lesions are draining. Typically, transmission requires direct and close contact with the person infected with plague.

4. **Intentional Dissemination**
   
   Intentional dissemination of plague would most likely occur as an aerosol release of the organism, resulting in pneumonic plague. Because of this route of exposure, exposed persons would likely develop primary pneumonic plague and would then be a potential source of person-to-person transmission.

F. Incubation Period

Generally, the incubation period for plague is 1–6 days with bubonic plague occurring 2–6 days and pneumonic plague occurring 1–3 days after an exposure.

G. Period of Communicability

Patients with pneumonic plague are communicable at the onset of symptoms. The infection generates an intense cough reflex, which readily disperses respiratory droplets capable of exposing close contacts. Patients with pneumonic plague are infectious until completion of at least 48 hours of appropriate antibiotic therapy.

Exudates from buboes contain viable *Y. pestis* organisms and patients with draining buboes are communicable until lesions are surgically excised or heal.

H. Treatment

Treatment includes prompt therapy with appropriate antibiotics and supportive care.
3. CASE DEFINITIONS

A. Clinical Description

Plague is transmitted to humans by fleas or by direct exposure to infected tissues or respiratory droplets; symptoms include fever, chills, headache, malaise, prostration, and leukocytosis with disease manifested in one or more of four principal clinical forms:

- Regional lymphadenitis (bubonic plague)
- Septicemia without an evident bubo (septicemic plague)
- Plague pneumonia, resulting from hematogenous spread in bubonic or septicemic cases (secondary pneumonic plague) or inhalation of infectious droplets (primary pneumonic plague)
- Pharyngitis and cervical lymphadenitis resulting from exposure to larger infectious droplets or ingestion of infected tissues (pharyngeal plague)

B. Laboratory Criteria for Diagnosis

1. Presumptive:
   - Elevated serum antibody titer(s) to *Yersinia pestis* fraction 1 (F1) antigen (without documented fourfold or greater change) in a patient with no history of plague vaccination or
   - Detection of F1 antigen in a clinical specimen by immunofluorescent assay

2. Confirmatory:
   - Isolation of *Y. pestis* from a clinical specimen or
   - Fourfold or greater change in serum antibody titer to *Y. pestis* F1 antigen

C. Case Definition (1996, 2010)

*Suspected*: a clinically compatible case without presumptive or confirmatory laboratory results

*Probable*: a clinically compatible case with presumptive laboratory results

*Confirmed*: a clinically compatible case with confirmatory laboratory results

4. DIAGNOSIS AND LABORATORY SERVICES

A. Laboratory Diagnosis

*Yersinia pestis* can be isolated from a variety of bodily fluids and tissues including bubo aspirates, blood, and tracheal/bronchial washings for bubonic, septicemic, and pneumonic forms, respectively. Specimens intended for culture should be taken before initiation of antibiotic treatment. Microbiology laboratory personnel should be alerted when *Y. pestis* is suspected, as laboratory acquired cases of plague have been reported. **Confirmatory laboratory testing must be performed by a reference laboratory such as the Washington State Public Health Laboratories.** If cultures do not detect the organism, serologic testing can be used to diagnose plague. Bipolar staining may be seen (Gram, Wright, Giemsa, or Wayson stain).
B. Tests Available at the Washington State Department of Health Public Health Laboratories (PHL)

PHL provide identification of *Y. pestis* from pure isolates as well as culturing of clinical specimens. Serologic tests are not performed at PHL but will be forwarded to the CDC for testing. PHL also perform rapid diagnostic testing in suspected bioterrorism situations. Contact Office of Communicable Disease Epidemiology (OCDE) for approval prior to collection and shipment of specimens.

Note that PHL require all clinical specimens have two patient identifiers, a name and a second identifier (e.g., date of birth) both on the specimen label and on the submission form. Due to laboratory accreditation standards, specimens will be rejected for testing if not properly identified. Also include specimen source and collection date.

C. Specimen Collection (and Shipping)

Consult OCDE prior to specimen preparation and shipment (206-418-5500). For details of specimen requirements and appropriate shipping procedures for *Y. pestis* see: [http://www.doh.wa.gov/ForPublicHealthandHealthcareProviders/PublicHealthLaboratories/MicrobiologyLabTestMenu](http://www.doh.wa.gov/ForPublicHealthandHealthcareProviders/PublicHealthLaboratories/MicrobiologyLabTestMenu)

**Serology:** Obtain one serum specimen as early in the illness as possible and a second sample 1 to 4 months after antibiotic therapy has ceased. Refrigerate specimens and transported cold. Avoid repeated freeze-thaw cycles. Submit specimens with a completed PHL serology examinations form: ([http://www.doh.wa.gov/Portals/1/Documents/5230/302-017-SerVirHIV.pdf](http://www.doh.wa.gov/Portals/1/Documents/5230/302-017-SerVirHIV.pdf)).

5. ROUTINE CASE INVESTIGATION

Interview the case or others who may be able to provide pertinent information.

A. Evaluate the Diagnosis

Review the clinical presentation and laboratory results. Confirmatory laboratory testing should be performed by a reference laboratory such as Washington State Public Health Laboratories (PHL). Facilitate submission of specimens to PHL for confirmation. For sporadic cases proceed with investigation after preliminary or confirmatory laboratory results are available. During an outbreak event or a potential bioterrorism situation, start investigation before laboratory results are available if needed.

B. Identify Potential Sources of Infection

Review clinical presentation and history to determine appropriate potential exposures (i.e., bubonic presentation would indicate most likely flea bite or animal carcass exposure; pneumonic presentation would indicate inhalation exposure). Investigate possible exposures during the period 1 to 7 days before onset, including a history of:

1. Travel to plague endemic areas (e.g., New Mexico, Arizona, Colorado, California, or parts of Washington or Oregon known to have plague activity);

2. Bites by fleas;
3. Contact with wild or commensal rodents or hunting/skinning wild animals;
4. Direct contact with a sick cat or dog (holding, petting, being bitten or scratched);
5. Contact with individuals with confirmed, probable or suspected pneumonic plague;
6. Work in microbiology laboratory.

C. Identify Close Contacts or Others Potentially Exposed to the Patient

1. Identify persons having household, hospital or other close contact with persons with pneumonic plague and educate them of symptoms of illness to facilitate diagnosis.
2. Identify laboratory workers and health care providers exposed to specimens or laboratory isolates and educate them of symptoms of illness to facilitate diagnosis.

Persons having household, hospital or other close contact with pneumonic plague cases should receive post-exposure antibiotic prophylaxis and be monitored for fever and cough for 7 days. See: http://www.cdc.gov/plague/healthcare/clinicians.html.

Guidelines for post-exposure prophylaxis after a bioterrorism attack are outlined in Inglesby TV, Dennis DT, Henderson DA, et al. Plague as a biological weapon: Medical and public health management. JAMA. 2000;283;2281–90.

D. Identify Potentially Exposed Persons

1. Identify and contact persons who participated with the case in any of the activities listed above. If any contacts are ill, inform them (or their physician) of possible exposure, in order to facilitate proper diagnosis and therapy.

E. Environmental Evaluation

1. If the source of infection appears to be wild rodents, the public should be informed of the risk of and how to avoid contact with potentially plague infected rodent populations.
2. If the source appears to be contact with plague-infected commensal rodents (i.e., rodent living in close association to humans, such as urban rats and pet rodents) or domestic cats, it can be assumed that this is due to spill over from a wild rodent population, and further investigation of the animal source is warranted.

F. Infection Control Recommendations/Case Management

1. Pneumonic plague: Droplet precautions are indicated for all patients until at least 48 hours after appropriate therapy has been initiated.
2. Bubonic plague: Hospitalized patients should be cared for using standard precautions.

6. MANAGING SPECIAL SITUATIONS

A. Bioterrorist Event

_Yersinia pestis_ is classified as a bioterrorism "category A" agent (of greatest concern) because it can be easily disseminated by aerosol, be transmitted from person to person (pneumonic plague) and cause severe illness and death. Suspect an intentional release (bioterrorist event) if unusual clusters of pneumonia occur in persons who are otherwise healthy or are in common buildings. _If plague is suspected immediately call Office of Communicable Disease Epidemiology (1-877-539-4344 or 206-418-5500)._
In event of a biological attack, antibiotic prophylaxis may be recommended for a suspected or known exposure to *Y. pestis*. For more information, see Recommendations of the Working Group on Civilian Biodefense, JAMA.2000;283;2281-90.

**8. ROUTINE PREVENTION**

**A. Immunization Recommendations**

There is currently no commercially vaccine available against plague in the United States.

**B. Routine Prevention**

1. **Avoid contact with sick or dead wild animals.** Wear gloves if handling dead animals. When skinning wild game keep gloves away from eyes and other mucous membranes. Thoroughly wash hands after handling wild game carcasses. Wild game meat should be cooked “well done” (to at least 74°C/165°F).

2. **Rodent-proof your home.** Eliminate sources of food and nesting places for rodents around homes, work places, and recreation areas; remove brush, rock piles, junk, cluttered firewood, and potential-food supplies, such as pet and wild animal food.

3. **Prevent your pets from contracting fleas.** Use flea-control products and don't allow pets to wander unsupervised. Ask your veterinarian for recommended flea-control brands and guidelines.

4. **Take precautions when outdoors.** Closely supervise your children and pets when spending time outside in areas with large rodent populations. Use insect repellent on your skin and clothing.

5. **If you suspect you have plague, consult a health care provider as soon as possible.**

**ACKNOWLEDGEMENTS**

This document is a revision of the Washington State Guidelines for Notifiable Condition Reporting and Surveillance published in 2002 which were originally based on the Control of Communicable Diseases Manual (CCDM), 17th Edition; James Chin, Ed. APHA 2000. We would like to acknowledge the Oregon Department of Human Services for developing the format and select content of this document.

**UPDATES**

January 2011: The Legal Reporting Requirements section has been revised to reflect the 2011 Notifiable Conditions Rule revision.

September 2013: reviewed, updated links

October 2015: reviewed, updated links
